XCS229i Problem Set 0

# XCS229i Problem Set 0 (Solutions): Linear Algebra and Multivariable Calculus

#### Notes:

- 1. These questions require thought, but do not require long answers. Please be as concise as possible.
- 2. If these questions or the notation they use seem foreign, please refer to the Linear Algebra Review and Reference notes.
- 3. If you have a question about this homework, we encourage you to post your question on the Problem Set 0 Slack channel.
- 4. This specific homework is *not graded*, but we encourage you to solve each of the problems to brush up on your linear algebra. Some of them may even be useful for subsequent problem sets.

Honor code: We strongly encourage students to form study groups. Students may discuss and work on homework problems in groups. However, each student must write down the solutions independently, and without referring to written notes from the joint session. In other words, each student must understand the solution well enough in order to reconstruct it by him/herself. In addition, each student should write on the problem set the set of people with whom s/he collaborated. Further, because we occasionally reuse problem set questions from previous years, we expect students not to copy, refer to, or look at the solutions in preparing their answers. It is an honor code violation to intentionally refer to a previous year's solutions.

## 1. [0 points] Gradients and Hessians

Recall that a matrix  $A \in \mathbb{R}^{n \times n}$  is symmetric if  $A^T = A$ , that is,  $A_{ij} = A_{ji}$  for all i, j. Also recall the gradient  $\nabla f(x)$  of a function  $f : \mathbb{R}^n \to \mathbb{R}$ , which is the *n*-vector of partial derivatives

$$\nabla f(x) = \begin{bmatrix} \frac{\partial}{\partial x_1} f(x) \\ \vdots \\ \frac{\partial}{\partial x_n} f(x) \end{bmatrix} \text{ where } x = \begin{bmatrix} x_1 \\ \vdots \\ x_n \end{bmatrix}.$$

The hessian  $\nabla^2 f(x)$  of a function  $f: \mathbb{R}^n \to \mathbb{R}$  is the  $n \times n$  symmetric matrix of twice partial derivatives,

$$\nabla^2 f(x) = \begin{bmatrix} \frac{\partial^2}{\partial x_1^2} f(x) & \frac{\partial^2}{\partial x_1 \partial x_2} f(x) & \cdots & \frac{\partial^2}{\partial x_1 \partial x_n} f(x) \\ \frac{\partial^2}{\partial x_2 \partial x_1} f(x) & \frac{\partial^2}{\partial x_2^2} f(x) & \cdots & \frac{\partial^2}{\partial x_2 \partial x_n} f(x) \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial^2}{\partial x_n \partial x_1} f(x) & \frac{\partial^2}{\partial x_n \partial x_2} f(x) & \cdots & \frac{\partial^2}{\partial x_n^2} f(x) \end{bmatrix}.$$

(a) Let  $f(x) = \frac{1}{2}x^TAx + b^Tx$ , where A is a symmetric matrix and  $b \in \mathbb{R}^n$  is a vector. What is  $\nabla f(x)$ ?

**Answer:** In short, we know that  $\nabla(\frac{1}{2}x^TAx) = Ax$  for a symmetric matrix A, while  $\nabla(b^Tx) = b$ . Then  $\nabla f(x) = Ax + b$  when A is symmetric. In more detail, we have

2

$$\frac{1}{2}x^{T}Ax = \frac{1}{2}\sum_{i=1}^{n}\sum_{j=1}^{n}A_{ij}x_{i}x_{j},$$

so for each  $k = 1, \ldots, n$ , we have

$$\frac{\partial}{\partial x_{k}} \frac{1}{2} \sum_{i=1}^{n} \sum_{j=1}^{n} A_{ij} x_{i} x_{j} \stackrel{(i)}{=} \frac{\partial}{\partial x_{k}} \frac{1}{2} \sum_{i=1, i \neq k}^{n} A_{ik} x_{i} x_{k} + \frac{\partial}{\partial x_{k}} \frac{1}{2} \sum_{j=1, j \neq k}^{n} A_{kj} x_{k} x_{j} + \frac{\partial}{\partial x_{k}} \frac{1}{2} A_{kk} x_{k}^{2}$$

$$\stackrel{(ii)}{=} \frac{1}{2} \sum_{i=1, i \neq k}^{n} A_{ik} x_{i} + \frac{1}{2} \sum_{j=1, j \neq k}^{n} A_{kj} x_{j} + A_{kk} x_{k}$$

$$= \sum_{i=1}^{n} A_{ki} x_{i}$$

where step (i) follows because  $\frac{\partial}{\partial x_k}A_{ij}x_ix_j=0$  if  $i\neq k$  and  $j\neq k$ , step (ii) by the definition of a partial derivative, and the final equality because  $A_{ij}=A_{ji}$  for all pairs i,j. Thus  $\nabla(\frac{1}{2}x^TAx)=Ax$ . To see that  $\nabla b^Tx=b$ , note that

$$\frac{\partial}{\partial x_k} b^T x = \frac{\partial}{\partial x_k} \sum_{i=1}^n b_i x_i = \frac{\partial}{\partial x_k} b_k x_k = b_k.$$

(b) Let f(x) = g(h(x)), where  $g : \mathbb{R} \to \mathbb{R}$  is differentiable and  $h : \mathbb{R}^n \to \mathbb{R}$  is differentiable. What is  $\nabla f(x)$ ?

**Answer:** In short, if g' is the derivative of g, then the chain rule gives

$$\nabla f(x) = q'(h(x))\nabla h(x).$$

Expanding this by components, we have for each i = 1, ..., n that

$$\frac{\partial}{\partial x_i} f(x) = \frac{\partial}{\partial x_i} g(h(x)) = g'(h(x)) \frac{\partial}{\partial x_i} h(x)$$

by the chain rule. Stacking each of these in a column vector, we obtain

$$\nabla f(x) = \begin{bmatrix} g'(h(x)) \frac{\partial}{\partial x_1} h(x) \\ \vdots \\ g'(h(x)) \frac{\partial}{\partial x_n} h(x) \end{bmatrix} = g'(h(x)) \nabla h(x).$$

(c) Let  $f(x) = \frac{1}{2}x^TAx + b^Tx$ , where A is symmetric and  $b \in \mathbb{R}^n$  is a vector. What is  $\nabla^2 f(x)$ ? **Answer:** We have  $\nabla^2 f(x) = A$ . To see this more formally, note that  $\nabla^2 (b^Tx) = 0$ , because the second derivatives of  $b_i x_i$  are all zero. Let  $A = [a^{(1)} \cdots a^{(n)}]$ , where  $a_i \in \mathbb{R}^n$  is an

*n*-vector (because A is symmetric, we also have  $A = [a^{(1)} \ a^{(2)} \ \cdots \ a^{(n)}]^T$ ). Then we use part (1a) to obtain

3

$$\frac{\partial}{\partial x_k} \left(\frac{1}{2} x^T A x\right) = a^{(k)T} x = \sum_{i=1}^n A_{ik} x_i,$$

and thus

$$\frac{\partial^2}{\partial x_k x_i} (\frac{1}{2} x^T A x) = \frac{\partial}{\partial x_i} a^{(k)^T} x = A_{ik}.$$

(d) Let  $f(x) = g(a^T x)$ , where  $g : \mathbb{R} \to \mathbb{R}$  is continuously differentiable and  $a \in \mathbb{R}^n$  is a vector. What are  $\nabla f(x)$  and  $\nabla^2 f(x)$ ? (*Hint:* your expression for  $\nabla^2 f(x)$  may have as few as 11 symbols, including ' and parentheses.)

Using the chain rule

**Answer:** We use the chain rule (part (1b)) to see that  $\nabla f(x) = g'(a^Tx)a$ , because  $\nabla(a^Tx) = a$ . Taking second derivatives, we have

$$\frac{\partial}{\partial x_i} \frac{\partial}{\partial x_j} = \frac{\partial}{\partial x_i} g'(a^T x) a_j = g''(a^T x) a_i a_j.$$

Expanding this in matrix form, we have

$$\nabla^2 f(x) = g''(a^T x) \begin{bmatrix} a_1^2 & a_1 a_2 & \cdots & a_1 a_n \\ a_2 a_1 & a_2^2 & \cdots & a_2 a_n \\ \vdots & \vdots & \ddots & \vdots \\ a_n a_1 & a_n a_2 & \cdots & a_n^2 \end{bmatrix} = g''(a^T x) a a^T.$$

#### 2. [0 points] Positive definite matrices

A matrix  $A \in \mathbb{R}^{n \times n}$  is positive semi-definite (PSD), denoted  $A \succeq 0$ , if  $A = A^T$  and  $x^T A x \ge 0$  for all  $x \in \mathbb{R}^n$ . A matrix A is positive definite, denoted  $A \succ 0$ , if  $A = A^T$  and  $x^T A x > 0$  for all  $x \ne 0$ , that is, all non-zero vectors x. The simplest example of a positive definite matrix is the identity I (the diagonal matrix with 1s on the diagonal and 0s elsewhere), which satisfies  $x^T I x = \|x\|_2^2 = \sum_{i=1}^n x_i^2$ .

(a) Let  $z \in \mathbb{R}^n$  be an *n*-vector. Show that  $A = zz^T$  is positive semidefinite.

**Answer:** Take any  $x \in \mathbb{R}^n$ . Then  $x^T A x = x^T z z^T x = (x^T z)^2 > 0$ .

(b) Let  $z \in \mathbb{R}^n$  be a non-zero n-vector. Let  $A = zz^T$ . What is the null-space of A? What is the rank of A?

**Answer:** If n=1, the null space of A is empty. The rank of A is always 1, as the null-space of A is the set of vectors orthogonal to z. That is, if  $z^Tx=0$ , then  $x\in \operatorname{Null}(A)$ , because  $Ax=zz^Tx=0$ . Thus, the null-space of A has dimension n-1 and the rank of A is 1.

(c) Let  $A \in \mathbb{R}^{n \times n}$  be positive semidefinite and  $B \in \mathbb{R}^{m \times n}$  be arbitrary, where  $m, n \in \mathbb{N}$ . Is  $BAB^T$  PSD? If so, prove it. If not, give a counterexample with explicit A, B.

**Answer:** Yes,  $BAB^T$  is positive semidefinite. For any  $x \in \mathbb{R}^m$ , we may define  $v = B^T x \in \mathbb{R}^n$ . Then

$$x^{T}BAB^{T}x = (B^{T}x)^{T}A(B^{T}x) = v^{T}Av \ge 0.$$

where the inequality follows because  $v^T A v > 0$  for any vector v.

## 3. [0 points] Eigenvectors, eigenvalues, and the spectral theorem

The eigenvalues of an  $n \times n$  matrix  $A \in \mathbb{R}^{n \times n}$  are the roots of the characteristic polynomial  $p_A(\lambda) = \det(\lambda I - A)$ , which may (in general) be complex. They are also defined as the the values  $\lambda \in \mathbb{C}$  for which there exists a vector  $x \in \mathbb{C}^n$  such that  $Ax = \lambda x$ . We call such a pair  $(x, \lambda)$  an eigenvector, eigenvalue pair. In this question, we use the notation  $\operatorname{diag}(\lambda_1, \ldots, \lambda_n)$  to denote the diagonal matrix with diagonal entries  $\lambda_1, \ldots, \lambda_n$ , that is,

$$\operatorname{diag}(\lambda_{1}, \dots, \lambda_{n}) = \begin{bmatrix} \lambda_{1} & 0 & 0 & \cdots & 0 \\ 0 & \lambda_{2} & 0 & \cdots & 0 \\ 0 & 0 & \lambda_{3} & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & \lambda_{n} \end{bmatrix}.$$

(a) Suppose that the matrix  $A \in \mathbb{R}^{n \times n}$  is diagonalizable, that is,  $A = T\Lambda T^{-1}$  for an invertible matrix  $T \in \mathbb{R}^{n \times n}$ , where  $\Lambda = \operatorname{diag}(\lambda_1, \ldots, \lambda_n)$  is diagonal. Use the notation  $t^{(i)}$  for the columns of T, so that  $T = [t^{(1)} \cdots t^{(n)}]$ , where  $t^{(i)} \in \mathbb{R}^n$ . Show that  $At^{(i)} = \lambda_i t^{(i)}$ , so that the eigenvalues/eigenvector pairs of A are  $(t^{(i)}, \lambda_i)$ .

**Answer:** The matrix T is invertible, so if we let  $t^{(i)}$  be the ith column of T, we have

$$I_{n \times n} = T^{-1}T = T^{-1} \begin{bmatrix} t^{(1)} \ t^{(2)} \ \cdots \ t^{(n)} \end{bmatrix} = \begin{bmatrix} T^{-1}t^{(1)} \ T^{-1}t^{(2)} \ \cdots \ T^{-1}t^{(n)} \end{bmatrix}$$

so that

$$T^{-1}t^{(i)} = \left[\underbrace{0 \cdots 0}_{i-1 \text{ times}} \ 1 \ \underbrace{0 \cdots 0}_{n-i \text{ times}}\right]^T \in \{0,1\}^n,$$

the ith standard basis vector, which we denote by  $e^{(i)}$  (that is, the vector of all-zeros except for a 1 in its ith position. Thus

$$\Lambda T^{-1}t^{(i)} = \Lambda e^{(i)} = \lambda_i e^{(i)}, \text{ and } T\Lambda T^{-1}t^{(i)} = \lambda_i Te^{(i)} = \lambda_i t^{(i)}.$$

A matrix  $U \in \mathbb{R}^{n \times n}$  is orthogonal if  $U^T U = I$ . The spectral theorem, perhaps one of the most important theorems in linear algebra, states that if  $A \in \mathbb{R}^{n \times n}$  is symetric, that is,  $A = A^T$ , then A is diagonalizable by a real orthogonal matrix. That is, there are a diagonal matrix  $\Lambda \in \mathbb{R}^{n \times n}$  and orthogonal matrix  $U \in \mathbb{R}^{n \times n}$  such that  $U^T A U = \Lambda$ , or, equivalently,

$$A = U\Lambda U^T$$
.

Let  $\lambda_i = \lambda_i(A)$  denote the *i*th eigenvalue of A.

(b) Let A be symmetric. Show that if  $U = [u^{(1)} \cdots u^{(n)}]$  is orthogonal, where  $u^{(i)} \in \mathbb{R}^n$  and  $A = U\Lambda U^T$ , then  $u^{(i)}$  is an eigenvector of A and  $Au^{(i)} = \lambda_i u^{(i)}$ , where  $\Lambda = \operatorname{diag}(\lambda_1, \ldots, \lambda_n)$ .

**Answer:** Once we see that  $U^{-1}=U^T$  because  $U^TU=I$ , this is simply a repeated application of part (3a).

(c) Show that if A is PSD, then  $\lambda_i(A) \geq 0$  for each i.

**Answer:** Let  $x \in \mathbb{R}^n$  be any vector. We know that  $A = A^T$ , so that  $A = U\Lambda U^T$  for an orthogonal matrix  $U \in \mathbb{R}^{n \times n}$  by the spectral theorem. Take the ith eigenvector  $u^{(i)}$ . Then we have

$$U^T u^{(i)} = e^{(i)},$$

XCS229i Problem Set 0 5

the ith standard basis vector. Using this, we have

$$0 \le u^{(i)^T} A u^{(i)} = (U^T u^{(i)})^T \Lambda U^T u^{(i)} = e^{(i)^T} \Lambda e^{(i)} = \lambda_i(A).$$
